## MONGODB AGGREGATE

RISMAYANA@POLTEKTEDC.AC.ID

## WHAT IS AGGREGATION

- Aggregations operations process data records and return computed results.
- Aggregation operations group values from multiple documents together, and can perform a variety of operations
  on the grouped data to return a single result.
- In SQL count(\*) and with group by is an equivalent of mongodb aggregation.

- The aggregate() Method
  - For the aggregation in MongoDB, you should use aggregate() method.
- Syntax
  - Basic syntax of aggregate() method is as follows
  - >db.COLLECTION\_NAME.aggregate(AGGREGATE\_OPERATION)

- \$project Used to select some specific fields from a collection.
- \$match This is a filtering operation and thus this can reduce the amount of documents that are given as input to the next stage.
- \$group This does the actual aggregation as discussed above.
- \$sort Sorts the documents.
- \$skip With this, it is possible to skip forward in the list of documents for a given amount of documents.
- \$limit This limits the amount of documents to look at, by the given number starting from the current positions.

```
Collection
db.orders.aggregate( [
    $group stage { $group: { _id: "$cust_id",total: { $sum: "$amount" } } }
   cust_id: "A123",
   amount: 500.
   status: "A"
                                      cust_id: "A123",
                                                                          Results
                                      amount: 500.
                                      status: "A"
   cust_id: "A123",
                                                                         _id: "A123",
   amount: 250,
                                                                         total: 750
   status: "A"
                                      cust_id: "A123",
                                      amount: 250,
                       $match
                                                         $group
                                      status: "A"
   cust_id: "B212".
                                                                         _id: "B212",
   amount: 200,
   status: "A"
                                                                         total: 200
                                      cust_id: "B212",
                                      amount: 200,
                                      status: "A"
   cust_id: "A123",
   amount: 300,
   status: "D"
      orders
```

Expression	Description	Example
\$sum	Sums up the defined value from all documents in the collection.	<pre>db.mycol.aggregate([{\$group : {_id :     "\$by_user", num_tutorial : {\$sum :     "\$likes"}}}])</pre>
\$avg	Calculates the average of all given values from all documents in the collection.	<pre>db.mycol.aggregate([{\$group : {_id :     "\$by_user", num_tutorial : {\$avg :     "\$likes"}}}])</pre>
\$min	Gets the minimum of the corresponding values from all documents in the collection.	<pre>db.mycol.aggregate([{\$group : {_id :     "\$by_user", num_tutorial : {\$min :     "\$likes"}}}])</pre>
\$max	Gets the maximum of the corresponding values from all documents in the collection.	<pre>db.mycol.aggregate([{\$group : {_id :     "\$by_user", num_tutorial : {\$max :     "\$likes"}}}])</pre>

Expression	Description	Example
\$push	Inserts the value to an array in the resulting document.	<pre>db.mycol.aggregate([{\$group : {_id :     "\$by_user", url : {\$push: "\$url"}}}])</pre>
\$addToSet	Inserts the value to an array in the resulting document but does not create duplicates.	<pre>db.mycol.aggregate([{\$group : {_id :     "\$by_user", url : {\$addToSet :     "\$url"}}}])</pre>
\$first	Gets the first document from the source documents according to the grouping. Typically this makes only sense together with some previously applied "\$sort"-stage.	<pre>db.mycol.aggregate([{\$group : {_id :     "\$by_user", first_url : {\$first :     "\$url"}}}])</pre>
\$last	Gets the last document from the source documents according to the grouping. Typically this makes only sense together with some previously applied "\$sort"-stage.	<pre>db.mycol.aggregate([{\$group : {_id :     "\$by_user", last_url : {\$last :     "\$url"}}}])</pre>

- The SELECT DISTINCT statement is used to return only distinct (different) values.
- Inside a table, a column often contains many duplicate values; and sometimes you only want to list the different (distinct) values.

```
Collection
db.orders.distinct( "cust_id" )
   cust_id: "A123",
   amount: 500,
   status: "A"
   cust_id: "A123",
   amount: 250,
   status: "A"
                                       [ "A123", "B212" ]
                        distinct
   cust_id: "B212",
   amount: 200,
   status: "A"
   cust_id: "A123",
   amount: 300,
   status: "D"
      orders
```

- Munculkan nama customer dan jumlah total yang telah dibayarkan selama ini!
- Munculkan 5 orang yang melakukan peminjaman paling banyak
- Munculkan film yang terdapat pada collection actor kemudian hitung jumlahnya
- Munculkan genre file yang terdapat pada collection payment kemudian hitung jumlahnya
- Munculkan customer yang berasal dari US
- Berapakah jumlah peminjaman yang terjadi pada tanggal 17 agustus 2005 yang berasal dari US
